Abstract: A series of novel tri-, tetra- and pentanuclear complexes composed of dinuclear LM₂ units (M=Co, Ni, Zn; L=24-membered macrocyclic hexaaza-dithiophenolate ligand) and ferrocene-carboxylate ([CpFeCH₂CO₂]⁻), 1,1'-ferro-cenedicarboxylate([Fe(C₅H₄-CO₂)₂]²⁻), acetylenedicarboxylate, terephthalate, isophthalate, and naphthalene diimide dicarboxylate groups is reported. The complexes have been synthesized and characterised by UV/Vis-, IR-spectroscopy, and X-ray crystallography. Each dicarboxylate dianion acts as a quadridentate bridging ligand linking two bioctahedral LM₂ units via μ₁,₃-bridging carboxylate functions to generate discrete dications with a central LM₂(O₂C-R-CO₂)M₂L core.

Keywords: coordination chemistry, amino-thiophenolate ligands, di- and tetranuclear complexes, ferrocene and naphthalene diimide derivatives, polynuclear complexes

1. Introduction

The chemistry of container molecules has developed extensively over the past two decades. Many container molecules such as calixarenes, resorcarenes, cyclodextrins, carcerands and glycourils have been invaluable in studying the fundamental principles of inclusion phenomena and consequently their use in separation science or drug delivery, as two examples of application. Importantly, the area has attracted interest in the field of supramolecular chemistry because the properties of such host–guest compounds are often different from those of their constituent components. By adjusting the size and form of the binding cavity it is often possible to complex co-ligands in unusual coordination modes, to activate and transform small molecules, or to stabilize reactive intermediates [1, 2]. One subclass are the metallated container molecules, in which metal ions and clusters are used as both a point of recognition and to give the container a well-defined structure. Such compounds also allow for an interplay of molecular recognition and transition-metal catalysis, and for the construction of more effective enzyme mimics. Of interest to the present work is the ability of metallocavitands to recognize and encapsulate difunctionalised molecules towards stabilising or enhancing the optical and electronic properties of redox- and photo-active compounds within a confined environment set up by two hemispheres.

The carboxylate group, RCO₂⁻, can bind to transition metals in a variety of coordination modes giving rise to complexes of great structural diversity [3]. Current activities focus on the coordination chemistry of polycarboxylate ligands, as these offer great potential in the construction of polynuclear aggregates [4] and extended coordination polymers with micro- and mesoporous structures [5–8] or catalytic properties [9]. In addition, polycarboxylate ligands are of importance as spin-coupling bridging ligands [10–17] in the rapidly expanding field of molecular magnetism [18, 19]. In this context, an enormous amount of literature has been generated concerning the distance dependence of magnetic exchange interactions between metal atoms linked by extended dicarboxylate ligands. Dinuclear copper complexes bridged by oxalate [20, 21] and terephthalate [22–24] dianions form, by far, the largest group of such systems, and it appears that the exchange interactions depend on the M···M distance [25], the relative orientation of the magnetic orbitals [26], and the degree of conjugation of the organic spacer unit [27, 28].

Scheme 1. Dinuclear acetate-bridged complexes of the hexaaza-dithiophenolate ligand L²⁻ and their label.
Recently, we reported the structures and magnetic properties of an isostructural series of bioctahedral [LMnII\(_2\)(OAc)]\(^{+}\) complexes, where L\(^{-}\) represents a macrodinucleating N\(_6\)S\(_2\) supporting ligand (Scheme 1) [29]. Intramolecular antiferromagnetic exchange interactions are present in the Mn\(_{\text{II}}\), Fe\(_{\text{II}}\) and Co\(_{\text{II}}\) complexes of this series with \(J\) values of \(-5.1\), \(-10.6\), and \(-2.0\) cm\(^{-1}\) (\(H = -2JS_1S_2\)). In contrast, in the corresponding Ni\(_{\text{II}}\) complex a ferromagnetic exchange interaction is present with \(J = +6.4\) cm\(^{-1}\).

### 2. Dicarboxylate dianions as a tetradeionate bridged ligands.

In view of the increasing interest in the targeted assembly of molecular-based magnetic materials using high-spin molecules of higher nuclearity [30–36], we considered it worthwhile to examine the possibility of linking pairs of dinuclear [LNi\(_{\text{II}}\)] units by dicarboxylate dianions to form tetranuclear species. In the present contribution we report the synthesis and crystallographic characterization of three tetranuclear nickel (II) complexes of the type [LNi\(_{\text{II}}\)dicarboxylateNi\(_{\text{II}}\)L], where “dicarboxylate” stands for acetylenedicarboxylate, terephthalate, or isophthalate dianions. A schematic representation of these complexes is shown in Scheme 2. These complexes differ by the distance between the centre of the Ni····Ni axis of the isostructural LNi\(_{\text{II}}\) subunits, their relative orientation, and the nature of the bridging ligands. The ability of the dicarboxylate dianions to mediate magnetic exchange interactions between the dinuclear subunits is examined and discussed in the light of their specific structural features.

![Scheme 2. Complexes prepared and their labels.](image)

6. \([\text{LNi}\(_{\text{II}}\)_2(acetylenedicarboxylate)]^{2+}\)
7. \([\text{LNi}\(_{\text{II}}\)_2(terephthalate)]^{2+}\)
8. \([\text{LNi}\(_{\text{II}}\)_2(isophthalate)]^{2+}\)

The complexes \([\text{LNi}\(_{\text{II}}\)_2(acetylenedicarboxylate)]^{2+}\) (6), \([\text{LNi}\(_{\text{II}}\)_2(terephthalate)]^{2+}\) (7), and \([\text{LNi}\(_{\text{II}}\)_2(isophthalate)]^{2+}\) (8) were readily prepared from the reaction of the dinuclear complex \([\text{LNi}\(_{\text{II}}\)_2(\mu-\text{Cl})]^{+}\) (1) and the corresponding triethylammonium dicarboxylate, prepared in situ from the acid and triethylamine in methanol in a 1:2 molar ratio, and isolated in high yield as the perchlorate or tetraphenylborate salts. The transformations are not simple substitution reactions, because simultaneous conformational changes of the supporting ligand L\(^{-}\) from the folded (C\(_{\text{s}}\)-symmetric) to the “bowl-shaped” (C\(_{\text{2v}}\)-symmetric) conformation take place (see Scheme 3) [37].

![Scheme 3. Schematic representation of the two ligand conformations in the chloro- and carboxylato-bridged complexes of (L).](image)

Nonetheless, linking of two [LNi\(_{\text{II}}\)]\(^{2+}\) fragments by the carboxylato ligands is a clean and facile step driven by the low solubility of the products.
All compounds gave satisfactory elemental analyses and their IR spectra are marked by the prominent asymmetric and symmetric carboxylate stretching frequencies around 1580 cm\(^{-1}\) and 1420 cm\(^{-1}\), diagnostic of \(\mu_1,3\)-bridging carboxylate functions [38]. The UV/Vis spectra of \(6-8\) in acetonitrile display two weak bands above 500 nm typical of octahedral Ni\(^{2+}\) (d\(^8\), S = 1) ions. The observed values compare closely with those of the acetato-bridged complex [LNi\(^{III}\)(OAc)]\(^+\) [29], indicative of a pseudo-octahedral N\(_3\)S\(_2\)O coordination environment about the metal ions. This is confirmed by single-crystal X-ray crystallography.

Crystals of \(6[BPh_4]_2\cdot2\text{MeCN}\cdot0.5\text{H}_2\text{O}\) were obtained by slow evaporation of an acetonitrile/ethanol (1:1) solution of \(6[BPh_4]_2\). The crystal structure is composed of tetranuclear [(LNi\(^{III}\))\(_2\)(acetylenedicarboxylate)]\(^{2+}\) dications, tetraphenylborate anions and acetonitrile and water solvates. Perspective drawings of the structure of \(6\) are depicted in Figure 1.

The acetylenedicarboxylate dianion acts as a tetradentate bridging ligand joining two dinuclear [LNi\(^{III}\)]\(^{2+}\) fragments through its carboxylate functions to give a tetranuclear Ni\(_2\)-(O\(_2\)CC\(-\equiv\)CCO\(_2\))-Ni\(_2\) array. Each nickel atom is surrounded in a highly distorted octahedral fashion by two sulfur atoms and three nitrogen atoms from the supporting ligand, and one oxygen atom from the acetylenedicarboxylate moiety. The Ni\(_2\)carboxylato planes are necessarily twisted by 86.3\(^\circ\) about the C≡C bond to relieve the unfavourable steric interactions between the bulky tBu groups of the two opposing [LNi\(^{III}\)]\(^{2+}\) subunits. The coligand is also slightly bent (C≡C 1.185(6) Å) such that the intramolecular distances between two nickel atoms of different dinuclear subunits within the tetranuclear complex range from 8.623(1) to 9.769(1) Å. The only system comparable to that of \(6\) is provided by the complex \([\text{Mo}_2(\text{DAniF})_3\text{O}_2\text{CC}\(-\equiv\)CCO\(_2\)]\), where DAniF = N,N’-di-p-anisylformamidinate, for which an intramolecular Mo···Mo distance of 9.537 Å has been reported [39]. There are no significant intermolecular interactions between the Ni\(^{III}\)\(^{2+}\) complexes within the lattice. The shortest intermolecular Ni···Ni distance is at 7.470(1) Å.

Figure 1. Left: Van der Waals plot of the [(LNi\(^{III}\))\(_2\)(\(\mu\)-acetylenedicarboxylato)]\(^{2+}\) dication in crystals of \(6[BPh_4]_2\cdot2\text{MeCN}\cdot0.5\text{H}_2\text{O}\). Middle: ORTEP representation of the core structure of 6 with the atom labeling scheme. Ellipsoids are represented at the 50% probability level. Right: Mutual orientation of the Ni\(_2\)carboxylato planes in 6.

The acetylenedicarboxylato ligand acts as a bifunctional linker coordinating to two octahedral [LNi\(^{III}\)]\(^{2+}\) entities via the carboxylate functions to generate a twisted Ni\(_2\)O\(_2\)C–C\(_4\)H\(_4\)–CO\(_2\)-Ni\(_2\) motif.
The \([\text{LNi}_2]^2\)\(^+\) subunits in 6 and 7 are structurally very similar, and the Ni–N, Ni–O, and Ni–S distances lie within very narrow ranges. As in 6, the \(t\)-Bu groups of the two opposing Ni\(_2\) clusters are forced to interlock to accommodate the terephthalato ligand. This causes tilting of the carboxylato planes that are rotated by 58.2° with respect to each other and by 19.1° and 39.1° with respect to the aromatic ring of the terephthalato coligand. Again, there are no intermolecular interactions between the tetranuclear complexes other than van der Waals contacts. The intramolecular Ni···Ni distances between the two dinuclear subunits are within the range 10.833(1) – 11.155(1) Å (mean 10.990(1) Å]. This is a typical value for terephthalato-bridged nickel(II) complexes [40,41].

Crystals of \([\text{BPh}_4]^2\)\(·4\)MeCN·EtOH are triclinic, space group P\(_1\). ORTEP views of the structure of the dication 8 and the central core are provided in Figure 3.
The isophthalate dianion is bonded to two \([LNi^{II}_{3}]^{2+}\) units through \(\mu_{1,3}\)-bridging carboxylate functions. The metal–ligand bond lengths within 8 reveal no anomalies and are very similar to those in 6 and 7. Strangely, the twisting of the carboxylato planes is less pronounced than in the previous cases. In fact, the two planes are almost coplanar with the phenyl ring of the bridging isophthalate dianion. The geometrical requirements of the isophthalate moiety with the two carboxylate functions in \textit{meta} orientation leads to a distance of 9.561 Å between the center of the Ni···Ni axes of the dinuclear units. This value should be compared with that of 10.712 Å in 7, where the two carboxylate functions are in \textit{para} positions. The present coordination mode of the isophthalate dianion forming a discrete Ni\(^{II}\) cluster is without precedence in the literature [42–44].

The magnetic properties of the three carboxylato-bridged complexes were examined in view of literature reports that conjugated dicarboxylate ligands are able to mediate long-range magnetic exchange interactions between paramagnetic metal ions [45]. The variable-temperature magnetic susceptibility data for 6[BPh\(_4\)]\(_2\), 7[BPh\(_4\)]\(_2\), and 8[BPh\(_4\)]\(_2\) were measured over the range 2.0-295 K using a SQUID magnetometer and an applied external magnetic field of 0.2 T. Plots of the temperature dependence of the effective magnetic moment for \(\mu_{\text{eff}}\) the three compounds are shown in Figure 4. The complexes have similar magnetic properties. At room temperature, the respective values of \(\mu_{\text{eff}}\) are 6.91 \(\mu_B\), 6.82 \(\mu_B\), and 7.13 \(\mu_B\) per tetranuclear complex. With decreasing temperature the \(\mu_{\text{eff}}\) values increase steadily to maximum values of 7.85 \(\mu_B\) (15 K), 7.71 \(\mu_B\) (15 K), and 8.03 \(\mu_B\) (25 K) for 6[BPh\(_4\)]\(_2\), 7[BPh\(_4\)]\(_2\), and 8[BPh\(_4\)]\(_2\), respectively. On lowering the temperature to 2.0 K, these values decrease slightly down to 7.57 \(\mu_B\), 7.02 \(\mu_B\), and 5.78 \(\mu_B\) at 2 K, presumably due to saturation effects or the zero-field splitting of nickel(II).

In summary, all three new compounds are discrete tetranuclear nickel(II) complexes composed of pairs of biocathedral \([LNi^{II}_{3}]^{2+}\) units united by a tetradentate dicarboxylate anion. The calixarene-like conformation adopted by the supporting ligand leads to an almost complete encapsulation of the Ni\(_4\)(O\(_2\)C–R–CO\(_2\))Ni\(_4\) core. As a consequence the Ni\(^{II}\) clusters are well-separated from each other in the solid state, featuring only intermolecular van der Waals contacts.
3. Redox-active ferrocenecarboxylates anions coordinated by dinuclear aminethiolate complexes

Polynuclear complexes composed of classical and organometallic complex fragments have attracted considerable attention in recent years [48, 49], owing to their rich redox chemistry [50, 51], the search for novel magnetic and electronic materials [52, 53], and potential applications in catalysis [51]. In addition, the presence of redox-active signalling groups and open coordination sites enables these compounds to be used as selective sensor molecules for target guest species [54–59]. So far, research in this area has mainly focused on conjugates built up of mononuclear LM complexes (L = chelate ligand) and suitably functionalized ferrocene derivatives [60–63]. Less attention has been paid to the use of discrete dinuclear LM$_2$ building blocks. The tetranuclear Mo$_4$ complexes containing two quadruply bonded Mo$_2$-formamidinate units linked by 1,1'-ferrocenedicarboxylate dianions may serve as rather rare examples of this class of compounds [64].

Recently, we described a series of dinuclear transition metal complexes supported by the macrocyclic hexaazadithiophenolate ligand L$^-$(Scheme 4). These complexes have a rich coordination chemistry since the [LM$_2$]$^{2+}$ fragments are able to coordinate a large variety of coligands such as Cl$^-$ [65], OH$^-$ [66], NO$_2^-$, NO$_3^-$, N$_3^-$ [67], BH$_4^-$ [68], and various carboxylates [69–71]. The extensive redox chemistry exhibited by dinuclear aminothiolate complexes [29] and the possibility of coupling these units into polynuclear arrays, led us to synthesize derivatives bearing ferrocenemono- and ferrocenedicarboxylate anions ([CpFeC$_5$H$_4$CO$_2$]$^-$ and [Fe-(C$_5$H$_4$CO$_2$)$_2$]$^{2-}$, Cp = cyclopentadienyl) as coligands. Our first attempts afforded a series of trinuclear [LM$_2$(O$_2$CC$_5$H$_4$FeCp)]$^+$ and pentanuclear [(LM$_2$)$_2$(O$_2$CC$_5$H$_4$)$_2$Fe]$^{2+}$ complexes. To our knowledge, these complexes represent the first class of compounds containing dinuclear aminothiolate complexes and redox-active ferrocenecarboxylates in the same molecule [72–75].

It was our aim to synthesize polynuclear complexes containing classical and organometallic complex fragments. Two types of complexes were considered: trinuclear [LM$_{II}$(O$_2$CC$_5$H$_4$FeCp)]$^+$ complexes and pentanuclear [(LM$_{II}$)$_2$(O$_2$CC$_5$H$_4$)$_2$Fe]$^{2+}$ compounds (here after abbreviated as M$_{II}$Fe and M$_{II}$Fe, respectively. Scheme 4 shows the complexes prepared and their labels.

9. [LCo$_{II}$(O$_2$CC$_5$H$_4$FeCp)]$^+$ 10. [LNi$_{II}$(O$_2$CC$_5$H$_4$FeCp)]$^+$ 11. [LZn$_{II}$(O$_2$CC$_5$H$_4$FeCp)]$^+$ 12. [(LCo$_{II}$)$_2$(O$_2$CC$_5$H$_4$)$_2$Fe)]$^{2+}$ 13. [(LNi$_{II}$)$_2$(O$_2$CC$_5$H$_4$)$_2$Fe)]$^{2+}$ 14. [(LCo$_{III}$Co$_{III}$(O$_2$CC$_5$H$_4$)$_2$Fe)]$^{4+}$

Scheme 4. Complexes prepared and their labels.

The trinuclear Co$_{II}$Fe and Ni$_{II}$Fe complexes, 9 and 10, were obtained in almost quantitative yield by reaction of the corresponding chloride complex [LM$_2$(μ-Cl)]$^+$ (M=Ni 1, Co 2) with triethylammonium ferrocenylmono-carboxylate (prepared in situ from CpFeC$_5$H$_4$CO$_2$H and triethylamine) in a 1:3 ratio in methanol at room temperature and isolated as perchlorate salts upon addition of LiClO$_4$. It should be noted that these reactions are not simple substitution reactions, because a simultaneous conformational change of the supporting ligand from a “partial-cone” to a “bowl-shaped” conformation takes place [76]. Since a chloro-bridged dizinc complex [LZn$_{II}$(μ-Cl)][ClO$_4$] is not yet known, the synthesis of the Zn$_{II}$Fe complex 11[ClO$_4$] required another starting material. Complex [LZn$_{II}$(μ-OAc)][ClO$_4$] (3[ClO$_4$]) was chosen due to its proven ability to readily exchange its acetato group for more hydrophobic carboxylate anions [71]. Indeed, when 3[ClO$_4$] is treated with a 10-fold excess of triethylammonium ferrocenecarboxylate in methanol at room temperature an exchange reaction takes place and 11[ClO$_4$] can be isolated as an analytically pure yellow powder after workup. The three perchlorate salts 9[ClO$_4$]–11[ClO$_4$] are air-stable solids that are readily soluble in polar aprotic organic solvents such as dimethylformamide, dichloromethane, acetone and acetonitrile but only slightly soluble in methanol or ethanol. The corresponding tetraphenylborate salts 9[BPh$_4$]–11[BPh$_4$] are formed within a few minutes upon addition of ethanol solutions of NaBPh$_4$ to acetonitrile solutions of the ClO$_4^-$ salts.
The pentanuclear Ni\textsuperscript{II}\textsubscript{2}Fe and Co\textsuperscript{II}\textsubscript{2}Fe complexes [(LM\textsubscript{2})(\mu-O\textsubscript{2}CC\textsubscript{5}H\textsubscript{4})\textsubscript{2}Fe\textsuperscript{2+} (M=Co (12), Ni (13)) were prepared in much the same way as 9 and 10: the chloride complexes 1 and 2 reacted smoothly with half an equivalent of triethylammonium 1,1\textsuperscript{-}ferrocenedicarboxylate (prepared in situ from the free acid and triethylamine) in methanol to give red-brown 12[ClO\textsubscript{4}]\textsuperscript{2-} and green 13[ClO\textsubscript{4}]\textsuperscript{2-}, respectively, in nearly quantitative yields. The coupling of the dicarboxylate dianions with the [LM\textsubscript{2}]\textsuperscript{2+} fragments is a clean and facile step driven forward by the low solubility of the products. The complexes are only slightly soluble in polar aprotic organic solvents such as DMF, dichloromethane, and acetonitrile and virtually insoluble in methanol or ethanol. Addition of NaB\textsubscript{ph} to suspensions of the perchlorate salts in acetonitrile/ethanol followed by concentration in vacuum provided the corresponding tetraphenylborate salts as analytically pure products.

We have also been able to isolate the two-electron-oxidized Co\textsuperscript{II}\textsubscript{2}Co\textsuperscript{III} form 14[ClO\textsubscript{4}]\textsubscript{4} of compound 12[ClO\textsubscript{4}]\textsubscript{2}. This mixed-valent complex was prepared as a black powder in good yields by oxidation of 12[ClO\textsubscript{4}]\textsubscript{2}; with 1 equiv of bromine in acetonitrile at 0°C followed by addition of a saturated ethanol solution of LiClO\textsubscript{4} and low-temperature vacuum concentration. In contrast to 12[ClO\textsubscript{4}]\textsubscript{2}, 14[ClO\textsubscript{4}]\textsubscript{4} exhibits excellent solubility in acetonitrile. Such solutions can be stored for several days at ambient temperature without noticeable decomposition. Attempts to prepare the analogous [(LNi\textsuperscript{II}Ni\textsuperscript{III})\textsubscript{2}(\mu-O\textsubscript{2}CC\textsubscript{5}H\textsubscript{4})\textsubscript{2}Fe\textsuperscript{2+} complex were not successful.

All compounds gave satisfactory elemental analyses and were characterized by appropriate spectroscopic methods (IR, NMR, UV/Vis -spectroscopy). The infrared spectra of the new complexes display absorptions due to the [LM\textsubscript{2}]\textsuperscript{2+} cations, tetraphenylborate anions, and acetonitrile molecules of solvent of crystallization. An ORTEP fragment of the Ni\textsuperscript{II}Fe complex 11 is shown in Figure 5.

The diamagnetic Zn\textsubscript{2}Fe complex 11 was characterized by NMR spectroscopy to determine its structure in solution. The \textsuperscript{1}H NMR spectrum shows the characteristic signal patterns for the [LZn\textsubscript{2}]\textsuperscript{2+} [78], and [CpFe(C\textsubscript{5}H\textsubscript{4}CO\textsubscript{2})\textsuperscript{2+}] [79], units indicating local C\textsubscript{2v} symmetry for 11. Particularly indicative of a stable 1:1 complex is the upfield shift of the tert-butyl resonance of the [LZn\textsubscript{2}] unit (0.25 ppm relative to 3). The resonances of the ferrocenecarboxylate are observed at \(3.40\) \textsuperscript{13}C NMR spectrum is also in accord with the proposed formulation showing two absorptions bands are detected at 342 and 440 nm; these are readily assigned to the d–d transitions of the [Fe(C\textsubscript{5}H\textsubscript{4}CO\textsubscript{2})\textsubscript{2}]\textsuperscript{+} unit and only 13 signals for the [LZn\textsubscript{2}]\textsuperscript{2+} moiety. The local C\textsubscript{2v} symmetry is suggestive of a dynamic averaging process in solution. A rapid rotation of the ferrocenyl group about the CpFeCp-CO\textsubscript{2}ZnL bond seems most likely. This motion would result in the coalescence of the respective signals and the time averaged C\textsubscript{2v} symmetry of the complex. The crystal structure determinations of 9 and 10 support this assumption.

The UV/Vis spectra of 9, 10, 12, and 13 display several weak bands above 500 nm typical of octahedral high-spin Co\textsuperscript{II} (d\textsuperscript{5}, S = \(\frac{3}{2}\)) and Ni\textsuperscript{II} (d\textsuperscript{8}, S=1) ions, respectively. The observed values closely compare with those of 4 and 5 again consistent with pseudo-octahedral N\textsubscript{3}S\textsubscript{2}O coordination environments around the metal atoms [69, 70]. For the Zn\textsubscript{2}Fe species 11[ClO\textsubscript{4}]\textsubscript{2} two absorptions bands are detected at 342 and 440 nm; these are readily assigned to the d–d transitions of the coordinated [CpFe(C\textsubscript{5}H\textsubscript{4}CO\textsubscript{2})\textsubscript{2}]\textsuperscript{+} unit. The feature at 440 nm is also evident in the electronic absorption spectrum of the Ni\textsubscript{2}Fe complex 10. In the UV spectrum of 11, this band is obscured by an intense ligand-to-metal charge-transfer transition (RS\textrightarrow;Co\textsuperscript{II}). The d–d transitions of the [Fe(\eta\textsuperscript{5}-C\textsubscript{5}H\textsubscript{4}CO\textsubscript{2})\textsuperscript{2+} unit in 12, 13 and 14 could not be located.

The UV/Vis spectra of the mixed-valent Co\textsuperscript{II}\textsubscript{2}Co\textsuperscript{III} complex 14 is dominated by two very intense absorptions at \(\approx 449\) and 681 nm; these are attributable to RS\textrightarrow;Co\textsuperscript{III} charge-transfer transitions. Such intense LMCT transitions are characteristic of thioloated-brided Co\textsuperscript{II}\textsubscript{2}Co\textsuperscript{III} complexes. The corresponding absorptions in [LCo\textsuperscript{II}(\mu-\text{OAc})\textsuperscript{2+}]\textsuperscript{2+}, for example, were observed at 460 and 710 nm [70]. It should be noted that the UV/Vis spectrum of 14 reveals no bands attributable to intercalation transfer (IT) bands. Complex 14 is therefore presumably class I in Robin and DayOs classification of mixed-valence species with distinct localized high-spin Co\textsuperscript{II} and low-spin Co\textsuperscript{III} sites [82]. This is confirmed by the crystal structure determination of 14[ClO\textsubscript{4}]\textsubscript{4}.

Crystals of 9[BPh\textsubscript{4}]\textsubscript{3}MeCN suitable for X-ray crystallography were grown by slow evaporation of a dilute 1:1 acetonitrile/ethanol solution of 9[BPh\textsubscript{4}]. The X-ray structure revealed the presence of well-separated [LCo\textsuperscript{II}(\mu-O\textsubscript{2}CC\textsubscript{5}H\textsubscript{4}FeCp)]\textsuperscript{2+} cations, tetraphenylborate anions, and acetonitrile molecules of solvent of crystallization. An ORTEP representation of the molecular structure of 9 is shown in Figure 5.
The ferrocenecarboxylate bridges the two Co atoms in a $\mu_{1,3}$-fashion, resulting in nonbonded Co···Fe separations of 5.884(1) and 5.753(1) Å. The Co···Co distance of 3.448(1) Å is the same as that in 4 [67]. The Cp rings are nearly parallel (angle between the normals of the Cp planes = 1.8(1)$^\circ$) and adopt an almost eclipsed conformation, with the torsional angle $\tau$ (defined as “CO$_2$-centroid-centroid-C(45)”$^{\prime}$) being 6.4(1)$^\circ$. The carboxylato plane is slightly twisted by 9.7$^\circ$ with respect to the Cp ring to which it is attached. The Fe-centroid distances are 1.656(6) and 1.646(6) Å for the carboxylated and the unsubstituted Cp rings, respectively; the mean Fe–ring (centroid) distance of 1.651(6) Å is, within experimental error, the same as that of 1.645(2) Å for ferrocene [83]. The bond lengths and angles around the Co atoms within the [LCoII$_2$]$^{2+}$ unit reveal no unusual features. The average Co–S, Co–N and Co–O bond lengths are at 2.018(3), 2.291(3), and 2.517(1) Å, respectively. Virtually the same distances are seen in the acetato-bridged complex 4 [67]. A large number of metal complexes containing ferrocenecarboxylate ligands have been structurally characterized [84–86]; to our knowledge, 9 is the first such complex supported by a dinuclear aminothiolate metallo ligand.

In contrast to the compound above, 10[BPh$_4$] recrystallized from acetonitrile/ethanol 1:1 with only one acetonitrile solvate molecule. Figure 6 shows the ferrocenecarboxylate to be coordinated to the [LNiII$_2$] unit in a manner identical to the situation found in 9 (Figure 5).
Thus, both NiII ions are six coordinate with three N and two S atoms from L2‾ and one O atom of a μ1,3-bridging ferrocenyl carboxylate group. In comparison to 9, the two Cp rings are perfectly eclipsed (tilt angle = 0.6(1)°) and the carboxylato plane is now coplanar with the Cp ring (τ = 2.88). The different τ values may be taken as evidence for an unhindered rotation of the coordinated ferrocene moiety about the O2C–Cp bond in the solution state. It should be noted in this respect that there are no intramolecular steric interactions between the ferrocene group and the tBu substituents. The short distances between C(45) and the p-electrons of the adjacent phenyl ring (d(C45)···centroid = 3.518 Å in 10 and 3.991 Å in 9) may be considered as weak CH···π hydrogen bonds. The Ni–O, Ni–N, and Ni–S distances of the [LNi2carboxylate] subunit in 10 are unexceptional and are very close to the corresponding distances in 5. Overall, the two structures clearly show that the [LM2]2+ units can expand their binding pockets sufficiently to accommodate μ1,3-bridging ferrocenecarboxylate ions.

Single crystals of the two compounds 12[BPh4]2·22/3MeCN·1/3H2O and 13[BPh4]2·1.75MeCN·EtOH·0.25H2O suitable for X-ray crystallography were each obtained by slow evaporation from an acetonitrile/ethanol/CH2Cl2 solution. The crystal structures consist of isolated [(LCoII)2(μ-O2CC5H4)2Fe]2+ dications (Figure 7), tetraphenylborate anions and various solvate molecules (MeCN, H2O, and EtOH), of which some are either severely disordered or not fully occupied.

Figure 7. a) ORTEP view of the [(LCoII)2(μ-O2CC5H4)2Fe]2+ dication 12 in crystals of 12[BPh4]2·22/3MeCN·1/3H2O. Hydrogen atoms are omitted for clarity. b) ORTEP representation of the core structure of 12 with the atom labelling scheme. Ellipsoids are represented at the 30% probability level.

The two compounds were found to be isomorphous in spite of differences in the number and type of solvate molecules. The following discussion will focus on the Co4IIFe complex 12. Metrical details for the Ni4IIFe complex 13 are reported in square brackets.

As can be seen in Figure 7b, the ferrocenylcarboxylate dianion links two [LCoII]2+ units via two μ1,3-bridging carboxylate functions. The [LCoII]2+ subunits in 12 and 4 are structurally very similar, and the Co–N, Co–O, and Co–S distances lie within very narrow ranges. The carboxylato groups on the Cp rings assume an anti-eclipsed conformation as manifested by a torsional angle τ (CO2-centroid-centroid-CO2) of 148.4° [148.3°]. The distance d between the centre of the Co···Co axes of the binuclear subunits amounts to 10.751 Å [10.749 Å], which is slightly smaller than the corresponding distance in [Mo2(DAniF)3]2[ferrocendicarboxylate] [64]. It should be noted that the Co-carboxylato planes are considerably tilted against each other (32.3°, [33.1°]) and also with respect to their corresponding Cp rings (22.4°, 10.1°; [22.4°, 10.0°]). This distortion from coplanarity relates to steric interactions between the tBu groups of the two opposing [LCoII]2+ subunits. The tert-butyl groups must interlock to accommodate the dicarboxylate ion. In ferrocenedicarboxylato complexes of sterically less encumbered supporting ligands the carboxylato planes are both coplanar with their parent Cp rings [87, 88].

The crystal structure of 14[ClO4]4·4H2O consists of [(LCoIII)2(μ-O2CC5H4)2Fe]4+ cations (Figure 8), ClO4− anions and water solvate molecules. There are two crystallographically independent but chemically almost identical molecules (labelled A and B) in the asymmetric unit; both have crystallographically imposed C2 symmetry with the iron atoms residing on crystallographic two-fold axes. The overall structure of complex 14 is very similar to that of its parent 12, featuring two binuclear LCo2 subunits linked by a tetradentate ferrocenedicarboxylate ion. Again, the carboxylato
groups are anti-eclipsed ($\tau = 148.6^\circ$ [136.9$^\circ$ (molecule B)] and considerably tilted against each other (48.2$^\circ$, [25.2$^\circ$]) and by 24.1$^\circ$ [12.6$^\circ$] with respect to their corresponding Cp rings. The distance $d$ between the centre of the Co···Co axes is 10.770 Å in molecule A and 10.322 Å in molecule B.

Figure 8. a) ORTEP view of the [(LCo$^{III}$Co$^{III}$)$_2$(μ-O$_2$CC$_5$H$_4$)$_2$Fe]$^{4+}$ tetracation (molecule A) in crystals of 14[ClO$_4$],4H$_2$O. Hydrogen atoms are omitted for clarity. b) ORTEP representation of the core structure of 14 with the atom labelling scheme. Ellipsoids are drawn at the 30% probability level.

The oxidation of 12 to 14 is accompanied by a significant shortening of the metal–ligand bond lengths around one Co atom in each binuclear subunit. This is in accord with the mixed-valent nature of 14 and the metal-centred nature of the oxidation of 12. Assignments of the trivalent and divalent Co ions are based on the bond distances around the cobalt atoms. Co1a [Co1b in molecule B] is assigned an oxidation state +II (d$^7$, high-spin), because the bond lengths are very similar to those in 12. The average Co–O, Co–N and Co–S bond lengths around Co2a [Co2b] are all significantly shorter at 1.884(4), 2.122(6), and 2.311(2) Å, respectively. These distances are too short for a six-coordinate Co$^{II}$ complex, but are in excellent accord with those of related low-spin Co$^{III}$N$_{n-}$S$_n$ [89, 90] and Co$^{III}$N$_3$S$_2$O [67] complexes. Interestingly, the oxidation of 12 is accompanied by an opening up of the intramolecular Co···Co distance to 3.523(1) Å. The Fe-Cp-ring (centroid) distances (1.653(6) Å and 1.651(6) Å) are not affected by the oxidation.

Evidently, the crystal structures of 12–14 clearly show that dinuclear LM$_2$ units can be coupled together by the 1,1’-ferrocendicarboxylate dianion. Moreover, the pentanuclear Co$_4$Fe complex 12 is even accessible in another oxidation state. The oxidation is metal-centered and occurs without gross structural changes of the parent complex 12. This finding paves the way for novel multi-redox systems composed of binuclear complex units and multifunctional metalorganic linkers which may find applications due to novel chemical or physico-chemical properties that are not seen for the individual components [91].

One facet of the present complexes is the presence of a redox-active ferrocene unit in close proximity to one or two redox-active [LM$_2$]$^{3+}$ groups. This feature suggests that electron transfer events can influence one another owing to the short distance (5.6±0.2 Å) between the redox centres. To determine whether this is the case, cyclovoltammetric studies have been carried out on the M$_2$Fe complexes $9$[ClO$_4$]$_2$–$11$[ClO$_4$]$_2$ and the Co$_4$Fe compound 14[ClO$_4$]$_4$. The cyclic voltammograms (CV’s) have been recorded in acetonitrile solution with tetra-n-butylammonium hexafluorophosphate as the supporting electrolyte. The electrochemical results are shown in Figure 9, and the redox potentials referenced versus SCE are collected in Table 1.
Figure 9. Cyclic voltammograms of the perchlorate salts of complexes 3–5, 9-11 and 14 in CH₃CN solution at 295K. Experimental conditions: 0.1M [nBu₄N][PF₆] supporting electrolyte, ca. 1x10⁻³ M sample concentration, Pt disk working, Pt wire auxiliary electrodes, Ag wire reference electrode, scan rate=100 mV s⁻¹. [Co(Cp)₂][PF₆] internal standard (E[CoCp₂⁺/CoCp₂]= – 0.94 V versus SCE).

³⁴ The CV’s were recorded at ambient temperature using 0.10 M [nBu₄N][PF₆] as supporting electrolyte at a scan rate of 100 mV s⁻¹. The data refer to the perchlorate salts. Sample concentration was ca. 1.0x10⁻³ M. All potentials are referenced versus the saturated calomel electrode (SCE).³⁵ Separation between the anodic (E⁺) and cathodic peaks (E⁻) of the redox wave (ΔEₚ =E⁺−E⁻).³⁶ Sodium salt.³⁷ Peak-potential value for irreversible processes.
The electrochemical data of 3–5, ferrocenecarboxylic acid and 1,1’-ferrocenedicarboxylic acid have been included for comparative purposes [92]. The CV of the Zn$_2$Fe complex 11[ClO$_4$] shows one reversible redox wave at +0.54 V that can be readily assigned to the oxidation of the ferrocene moiety, since it is absent in the CV of [LZn$_2$(OAc)] [ClO$_4$] (3[ClO$_4$]). Interestingly, the complexation of [CpFe(C$_5$H$_4$COO)]$^-$ causes an anodic potential shift of 90 mV in the reversible redox wave of the ferrocene moiety. It is assumed that this potential shift results from the electrostatic repulsion (Coulomb) effect between the two Zn$^{2+}$ ions bonded by the macrocycle and the positively charged ferrocenium centre. Thus complexation of [CpFe(C$_5$H$_4$COO)]$^-$ by the dipositively charged [LZn$_2$]$^{5+}$ unit makes the ferrocenyl group more difficult to oxidize. Curiously, an anodic shift of ≈140 mV for the peak potential for the second, irreversible ligand-based oxidation (formally a RS$^-$→RS transition) [29] that follows the ferrocenyl centred oxidation is also evident. In this case it is the additional positive charge on the ferrocene that causes the thiolate sulfur atoms to be oxidized at a higher potential. The redox-processes for 11[ClO$_4$] are summarized in Scheme 5.

Scheme 5. Assignment of redox processes in 9–11 and 14

The CV of the Co$_2$Fe complex 9 exhibits three reversible one-electron redox waves which can be assigned to i) a metal-centered Co$^{II}$→Co$^{III}$ oxidation yielding the mixed-valent dication [LCo$^{III}$Co$^{II}$(O$_2$CC$_5$H$_4$FeCp)]$^{2+}$ (9$^{2+}$) at 0.20 V, ii) a metal-centered Co$^{III}$→Co$^{IV}$ oxidation at 0.59 V forming tricationic [LCo$^{III}$$_2$(O$_2$CC$_5$H$_4$FeCp)]$^{3+}$ (9$^{3+}$), and iii) oxidation of the metalorganic unit generating tetracationic [LCo$^{III}$$_2$(O$_2$CC$_5$H$_4$Fe$^{II}$FeCp)]$^{4+}$ (9$^{4+}$) at 0.81 V. These assignments are supported by the electronic absorption spectra of the corresponding di-, tri- and tetracations generated in situ by successive chemical oxidations of 9$^+$ with 0.5, 1.0, and 1.5 equiv of bromine in acetonitrile solution (Figure 10); the characteristic absorption maxima at 388 and 467 nm of the ferrocinium ion are not observed before the third oxidation step.

![Figure 10. UV/Vis spectra of 9 (-----), 9$^{2+}$ (·····), 9$^{3+}$ (-----), and 9$^{4+}$ (──) in acetonitrile generated by chemical oxidation of [LCo$^{II}$(μ-O$_2$CC$_5$H$_4$FeCp)][ClO$_4$] (9[ClO$_4$]) with 0.5, 1.0, and 1.5 equiv of Br$_2$, respectively.](image-url)

The potential shift for the oxidation of the ferrocenyl unit in 9$^{3+}$ ($\Delta E = +0.37$ V) is significantly larger than in 11$^+$. The significantly larger shift is likely to be a result of the higher positive charge of the [LCo$^{III}$_2]$^{5+}$ fragment to which the Fe$^{II}$(Cp)(C$_5$H$_4$COO$^-$) unit is attached in 9$^{3+}$. 69
The CV of Ni₂Fe compound 10 reveals two electrochemically reversible and one irreversible redox waves, which by comparison with the CV of 5 [29] are tentatively assigned to i) a metal-centred Ni²⁺Ni⁶⁺ → Ni²⁺Ni⁶⁺ oxidation yielding the mixed-valent dication [LNi²⁺Ni⁶⁺(O₂CC₅H₄FeIIICp)]²⁺ (5⁺) at 0.53 V, ii) the oxidation of the metal organic unit forming [LNi²⁺Ni⁶⁺(O₂CC₅H₄FeIIICp)]³⁺ (5³⁺) at 0.71 V, and iii) the oxidation of the thiophenolate sulfur atoms yielding a nickel bound thyl radical at 1.59 V. Anodic shifts in the second and third redox waves are clearly discernible, confirming the above findings that the electron transfer events of the ferrocenyl moiety and the binuclear subunit influence one another. The fact that the potential shifts are not so pronounced than in 9 is in good agreement with the smaller positive charges of the participating species. It should be noted that all oxidation products of 9 and 10 are only stable on the time scale of a cyclic voltammetry experiment. Attempts to prepare these compounds by electrochemical or chemical oxidation led to unidentified decomposition products. Thus, while some of the above oxidations appear electrochemically reversible, they are all chemically irreversible.

Of the tetranuclear complexes, only complex 14[ClO₄]₄ had sufficient solubility (due to its higher charge) to examine its electrochemical properties by cyclic voltammetry. The CV shows two quasi-reversible redox waves. On the basis of the crystal structure of 14[ClO₄]₄, the first redox wave at 0.22 V can be assigned to a two-electron reduction of 14⁺⁺ yielding the fully-reduced Co²⁻Fe form 14²⁺ (which is assumed to be identical with 12). The other wave at 0.53 V can be attributed to a metal-centred two-electron oxidation process yielding the fully oxidized Co³⁺Fe form [(LCo⁳⁺)(Fe(Cp))]⁶⁺ (14⁶⁺). The observed potential values are almost identical with those in 4 [67], indicating that the oxidation/reduction processes at one [LCo₂] unit do not influence the ones that occur at the other. In other words, the two dinuclear cobalt(II) subunits behave as two independent redox-groups. That is fully consistent with the large distance between the two subunits and the fact that the electrostatic (Coulomb) interactions decrease rapidly with increasing distance between the redox sites. The redox wave for the oxidation of the [Fe(C₅H₄CO₂)₂]⁻ unit in 14 could not be detected. We assume that it is obscured by the redox waves at 0.53 V.

There have been many reports in the literature that a charged subunit can influence the redox properties of an adjacent ferrocene group [93]; to our knowledge, complexes 9–11 represent the first examples for a system in which the redox properties of a ferrocenecarboxylate-based ligand is modified by dinuclear aminethiophenolate complexes.

The magnetic properties of the pentanuclear Ni₄Fe complex 13[BPh₄]₂ were examined in view of literature reports that conjugated dicarboxylate ligands can mediate long-range magnetic exchange interactions [45]. Figure 11 displays the temperature dependence of the effective magnetic moment for 13[BPh₄]₂. The effective magnetic moment increases from 6.88 μₘ at 295K to a maximum value of 7.70 μₘ at 25K. On lowering the temperature further the magnetic moment decreases to 7.08 μₘ at 2 K. Although the effective magnetic moment at 25K is smaller than expected for the spin-only value of 9.84 μₘ for Sₚ = 4 resulting from the ferromagnetic coupling of four Ni³⁺ ions (Sᵢ = 1, g = 2.20), it is larger than the value of 6.22 μₘ calculated for four noninteracting Ni²⁺ ions. This behaviour indicates the presence of weak ferromagnetic exchange interactions between the Ni³⁺ ions in the binuclear subunits but negligible - if any - coupling across the metallocene dicarboxylate bridge. Considering the long distance between the nickel(II) ions, this is not surprising.
4. Functionalized naphthalene diimide as a bifunctional linker

We and others have been working with naphthalene diimides as a suitable class of chemically robust redox- and photo-active units with which to explore molecular electronic applications [94, 95]. The naphthalene diimides are a compact, electron-deficient class of aromatic compounds that allow further fine-tuning of their optical properties (absorbance and emission) via suitable core functionalization [95]. The consideration that naphthalene diimides can act as ideal components for the creation of supramolecular functional materials has transpired as a result of their more desirable electronic and spectroscopic properties relative to pyromellitic diimides and better fabrication properties than the perylene diimide dyes, the latter being a result of their enhanced solubility properties. Naphthalene diimides (NDI) undergo single reversible one-electron reduction (chemically and electrochemically) at modest potentials (NDI: $E^{\text{red}}_{1/2} \approx 1.1 \text{ V vs.} \text{Fc/Fc}^+$) to form stable radical anions in high yield [96]. They are seen as attractive redox-active units because of their electronic complementarity to ubiquinones [97] which make them excellent components for studying photoinduced electron transfer [98]. Here we examine the interplay of a binucleating nickel(II) cavatand [LNi$_2$(μ-Cl)][ClO$_4$] (1) with a naphthalene diimide 16 bearing two β-alanyl groups [99, 100] (Scheme 6).

To our knowledge, complex 15 represents the first example of a supramolecular ensemble containing dinuclear amine-thiolate complexes and redox-active organic components within the same molecule.

Reaction of 1 with half an equivalent of 16 with NEt$_3$ in MeOH at r.t. leads to the immediate formation of a green solution. After the addition of a ten-fold excess of LiClO$_4$ a green microcrystalline solid, characterized as the 2:1 complex 15[ClO$_4$]$_2$, is obtained in 72% yield. The perchlorate salt of 15$^{2+}$ is an air-stable solid that is readily soluble in polar aprotic solvents such as N,N-dimethylformamide, dichloromethane and acetonitrile, but virtually insoluble in methanol and water. The electrospray ionization mass spectrum (ESI-MS, positive mode) of a dilute CH$_2$Cl$_2$ solution of 15 [ClO$_4$]$_2$ exhibits a molecular ion peak with the correct isotopic distribution for the dication $15^{2+}$ (m/z = 989.36). Two prominent vibration bands are seen in the IR, as in other carboxylato-bridged Ni$_2$ complexes of (L)$_2^-$, at 1583 and 1423 cm$^{-1}$ [65, 67]. These are assigned to the antisymmetric and symmetric carboxylate stretching modes, respectively, of a μ$_1,3$-bridging carboxylate function. The ν(CO) stretching frequencies of the carboxamide functions of [16-2H]$^2$-$^2$ are also clearly visible at 1706 and 1669 cm$^{-1}$.

The dual coordination mode of the naphthalene diimide unit is further demonstrated by UV/Vis spectroscopy. The UV/Vis spectrum of a solution of 15[ClO$_4$]$_2$ in CH$_2$Cl$_2$ is displayed in Figure 12 and that of [LNi$_2$(OAc)]$5$[ClO$_4$] is shown for comparison. Complex 15$^{2+}$ reveals five well-resolved UV bands at 272, 306, 336, 360 and 380 nm, the former three of which are attributable to the π-π* transitions within the thiophenolate units of the [Ni$_2$L]$^{2+}$ fragments. Their intensity is approximately twice as large as those of the model compound 5$^+$, which is in good agreement with the formulation of compound 15$^{2+}$ as a 2:1 complex.

Scheme 6. Schematic representation of the encapsulation of the di-functionalised naphthalene diimide 16 by a binucleating metallocavitand 1 to yield the complex 15[ClO$_4$]$_2$. 

of a dilute CH$_2$Cl$_2$ solution of 15 [ClO$_4$]$_2$ exhibits a molecular ion peak with the correct isotopic distribution for the dication $15^{2+}$ (m/z = 989.36). Two prominent vibration bands are seen in the IR, as in other carboxylato-bridged Ni$_2$ complexes of (L)$_2^-$, at 1583 and 1423 cm$^{-1}$ [65, 67]. These are assigned to the antisymmetric and symmetric carboxylate stretching modes, respectively, of a μ$_1,3$-bridging carboxylate function. The ν(CO) stretching frequencies of the carboxamide functions of [16-2H]$^2$-$^2$ are also clearly visible at 1706 and 1669 cm$^{-1}$.

The dual coordination mode of the naphthalene diimide unit is further demonstrated by UV/Vis spectroscopy. The UV/Vis spectrum of a solution of 15[ClO$_4$]$_2$ in CH$_2$Cl$_2$ is displayed in Figure 12 and that of [LNi$_2$(OAc)]$5$[ClO$_4$] is shown for comparison. Complex 15$^{2+}$ reveals five well-resolved UV bands at 272, 306, 336, 360 and 380 nm, the former three of which are attributable to the π-π* transitions within the thiophenolate units of the [Ni$_2$L]$^{2+}$ fragments. Their intensity is approximately twice as large as those of the model compound 5$^+$, which is in good agreement with the formulation of compound 15$^{2+}$ as a 2:1 complex.
Figure 12. Electronic absorption spectra of $\text{15[ClO}_4\text{]}_2$ (black) and model $\text{5[ClO}_4\text{]_2}$ (grey) in CH$_2$Cl$_2$ solution (sample concentration = $10^{-4}$ M). The inset shows the absorptions of $\text{15[ClO}_4\text{]_2}$ and $\text{5[ClO}_4\text{]_2}$ attributed to weak d–d absorptions (sample concentration = $10^{-3}$ M).

The low energy bands at 360 and 380 nm which are typical for naphthalene diimides [96] further confirm the identity of complex $\text{15^{2+}}$. The UV/Vis spectrum also reveals two weak d–d absorption bands at 644 and 1122 nm typical of octahedral Ni$^{II}$ in an N$_3$S$_2$O$_2$ carboxylate environment. The observed values closely compare with those of $\text{5^+}$ (see inset in Fig. 12) again consistent with pseudo-octahedral N$_3$S$_2$O coordination environments around the metal atoms. All these findings strongly indicate that the tetranuclear complex $\text{15^{2+}}$ retains its integrity in solution.

To determine whether $\text{15^{2+}}$ exhibits electron transfer events due to the NDI unit and the [Ni$_2$L]$_2^{2+}$ groups, cyclic voltammetric studies have been carried out on $\text{15[ClO}_4\text{]_2}$ in DMF solution using 0.10 M [nBu$_4$N][PF$_6$] as the supporting electrolyte (Fig. 13). The CV of the Ni$_4$ complex $\text{15[ClO}_4\text{]_2}$ shows three redox waves at -1.62, -1.04 and 0.15 V, respectively, vs. ferrocenium /ferrocene (Fc$^+$/Fc). The processes at -1.04 and -1.62 V correspond to the reduction of the dication $\text{15^{2+}}$ to $\text{15^{+}}$ (bearing the radical anion $\text{16^{-}}$) and the reduction of $\text{15^{+}}$ to neutral $\text{15}^{-}$ (bearing the doubly reduced NDI ligand), respectively. Upon reduction of $\text{15^{2+}}$ by either electrochemical or chemical means (Na$_2$S$_2$O$_4$/H$_2$O) the colour of the complex changes to deep mauve which (in the absence of air) persists in solution over 3 h indicative of radical anion formation. The redox wave located at 0.15 V on the other hand is tentatively assigned to a two-electron metal-centered Ni$^{II}$$\rightarrow$Ni$^{III}$ oxidation yielding the mixed-valent tetrametallic tetracation $[(\text{Ni}^{III}\text{Ni}^{II}L))_2(\text{16})]^{4+}$ ($\text{15^{4+}}$). The redox-wave for the oxidation of the tetracation $\text{15^{4+}}$ to the hexacation $\text{15^{6+}}$ (formally a Ni$^{II}$$\rightarrow$Ni$^{III}$ process as seen for complex $\text{5[ClO}_4\text{]_2}$) could not be detected. We assume that it is obscured by the redox-waves associated with the oxidation of the solvent.

Figure 13. Cyclic voltammogram of $\text{15[ClO}_4\text{]_2}$ in DMF at 295K. Experimental conditions: $[\text{15[ClO}_4\text{]_2}] = 10^{-3}$ M, Pt-disk working electrode, Ag wire reference electrode, 0.1 M [nBu$_4$N][PF$_6$], scan rate = 200 mV s$^{-1}$.
The redox-processes are summarised in Scheme 7.

\[
\begin{align*}
\text{[(Ni}^{II}_{2}L)_{2}(2^{\text{-}})]^{2+} & \quad + e^{-} \quad \text{(-1.62 V)} \\
15^{2+} & \quad - e^{-} \\
\text{[(Ni}^{II}_{2}L)_{2}(2^{\text{-}})\text{]}^{4+} & \quad + 2e^{-} \quad \text{(0.15 V)} \\
15^{4+} & \quad - 2e^{-}
\end{align*}
\]

The observed potentials for the reduction of the naphthalene diimide ligand 16 are ca. 100 mV more negative than those reported for other N-alkylated naphthalene diimides [95]. Though there are many factors that could contribute to this significant effect, a simplistic thermodynamic view would argue that the influence of the aromatics within the cavitand structure on the NDI upon encapsulation is a strong contributor. The single peak value of 0.15 V measured for the Ni²⁺→Ni³⁺ oxidation steps is almost identical to that observed for the model \([\text{NiClO₄]}_{2}\) (E = 0.11 V vs. Fc⁺/Fc⁻) [29], indicating that the oxidation/reduction process on one [Ni,L] unit does not influence the processes that occur at the other site [75]. In other words, the two dinuclear nickel(II) subunits behave as two independent redox-groups. This observation is consistent with the large distance of ca. 19 Å between the two subunits (see Fig. 14(a)) and the fact that the electrostatic (Coulombic) interactions decrease rapidly with increasing distance between two redox-sites.

The radical anion of the NDI within 15⁻ is characterised by a set of intense and characteristic visible and near-infrared (NIR) absorption bands. Thus, the electronic spectrum of a solution of 15⁻ in DMF (generated by reduction of 15²⁺ with an aqueous Na₂S₂O₄ solution) shows bands at 270 (50236), 283 (26840), 329 (28917), 373sh (1072), 400sh (8360), 474 (31586), 607 (9019), 682 (4738) and 756 nm (6618 M⁻¹ cm⁻¹). Similar values have been reported for other NDI radicals [95].

Figure 14. (a) van der Waals representation of the molecular structure of the dication 15²⁺ in crystals of 15[BPh₄]₂. (b) Asymmetric unit of 15²⁺ with thermal ellipsoids drawn at the 30% probability level, hydrogen atoms and MeCN solvent are omitted for clarity. (c) Packing of individual molecules in the crystal lattice of 15[BPh₄]₂ (BPh₄⁻ anions and solvent acetonitrile molecules are omitted for clarity).
The composition of the assembly as $15^+$ was confirmed by a single-crystal X-ray structure determination, as the tetraphenylborate salt $15[BPh_4]_2$ (prepared by salt metathesis of $15[ClO_4]_2$ with NaBPh$_4$). Crystals of $15[BPh_4]_2$·CH$_2$CN suitable for X-ray crystallography were grown by recrystallisation from MeCN. Fig. 14 displays a van der Waals representation of the monoclinic dication $15$ formed within a triclinic crystal with space group $P1$. The dicarboxylate acts as a tetradeutate bridging ligand joining two dinuclear $[LNi_2^2]^{2-}$ fragments through its carboxylate functions. Each Ni atom is thus surrounded in a highly distorted octahedral fashion by two sulfur atoms and three nitrogen atoms from the supporting ligand $L^2$– and one oxygen atom from the carboxylate groups of $[16-2H]^{2-}$.

The macrocycle assumes a rigid bowl-shaped conformation very similar to that found for $[Ni,L(\mu-OAc)][ClO_4]$ (5) [29]. As a consequence, the $[Ni,L]^2$ subunits in 15 and 5 are structurally very similar, and the Ni–N and Ni–S distances lie within very narrow ranges. The NDI ligand assumes a planar conformation and the Ni–O planes are only slightly folded with respect to the NDI plane (folding angle = 15.1°). The NDI unit is not coplanar with the aromatic rings of the cavity, the folding angles between the planes of the two aromatic rings of the cavity and the plane through the NDI unit being 31.8° and 53.9°, respectively. The Ni···Ni distance of 3.481(1) Å is practically the same as that in 5. The distance between the center of the Ni···Ni axes of the binuclear subunits are amounts to 19.010(1) Å.

Complex 15 is unique in the sense that its naphthalene diimide coligand is included within the two metallocavitands. To the best of our knowledge, this is the first structural report of such an inclusion complex. In contrast to “free” NDI compounds, no π–π-stacking interactions involving the NDIs are present in 15, a fact attributable to the steric shielding of the $[Ni,L]^2$–units. This feature is no doubt responsible for the enhanced solubility of the complex 15 over 16. Furthermore, limiting the ability for NDIs to stack has important implications for their use in molecular electronics by limiting aggregation and hence the excimer emission found in many systems [101–103].

The structure is stabilised by intermolecular CH···π interactions as indicated by relatively short distances between the $\beta$Bu methyl groups and the naphthalene rings (d (C$^\text{N}$(methyl)···centroids naphthalene ring): 3.618 Å (C36'···X1a), 3.979 Å (C37'···X1a), 3.663 Å (C37'···X1b), 3.902 Å (C36'···X1b) [104]. These interactions lead to a two-dimensional interdigitated packing of the molecules as shown in Figure 14(c). The shortest intermolecular Ni···Ni distance is at 7.470(1) Å. The structure lacks any intermolecular or intramolecular π–π stacking interactions. The closest distances between the centre of the Ni unit and the centre of the aromatic rings are 7.633 and 10.018 Å, respectively. The BPh$_4$ counterions are well separated from the dication $15^+$.

5. Conclusions

In summary, a series of novel tri-, tetra- and pentanuclear complexes composed of dinuclear LM$_2$ units (M=Co, Ni, Zn; L$^2$– represents a macrocyclic hexazadithiophenolate ligand) and ferrocencarboxylate (CpFeC$_5$H$_4$CO$_2$–), 1,1’-ferrocenedicarboxylate(FeC$_6$H$_5$-CO$_2$–), acetylenedicarboxylate, terephthalate, isophthalate, and naphthalene diimide dicarboxylate groups is reported. The complexes, have been synthesised and characterized by UV/Vis-, IR-spectroscopy, and X-ray crystallography. Each dicarboxylate dianion acts as a quadridentate bridging ligand to generate discrete dications with a central $M_2$(O$_2$C-R-CO$_2$)$_2$L$_2$ core. The structures differ mainly in the distance between the centre of the Ni···Ni axes of the isostructural LNi$_2$ units (8.841(1) Å in $6[BPh_4]_2$, 10.712(1) in $7[BPh_4]_2$, and 9.561(1) in $8[BPh_4]_2$) and the tilting angle between the two NiO$_2$ planes (86.3° in $6[BPh_4]_2$, 85.4° in $7[BPh_4]_2$, and 20.9° in $8[BPh_4]_2$). Magnetic susceptibility measurements on the complexes over the range 2.0 – 295K reveal the presence of weak ferromagnetic exchange interactions between the Ni$^{II}$ ions within the dinuclear subunits with values for the magnetic exchange constant $J$ of 23.10, 18.06, and 14.16 cm$^{-1}$ for $6[BPh_4]_2$, $7[BPh_4]_2$, and $8[BPh_4]_2$, respectively (H = –2J/$S_i$,$S_j$). The magnitude of the exchange interaction $J$ across the dicarboxylate bridges is in all cases less than 0.1 cm$^{-1}$, suggesting that no significant interdimer exchange coupling occurs in $6[BPh_4]_2$, $7[BPh_4]_2$, and $8[BPh_4]_2$.

The first members of a new class of polynuclear transition metal complexes composed of classical [LM$_2$] units (M=Co, Ni, Zn) and ferrocencycarboxylate groups were synthesised and characterized. Mixed-valent $[1(LCo(CO$_3$)$_2$)$\cdot$(O$_2$C-$\cdot$C$_4$-$\cdot$H$_4$)$]Fe^{\text{IV}}$ (14) was prepared by oxidation of 12 with bromine. X-ray crystal determination of complexes $9[BPh_4]_2$, $10[BPh_4]_2$, $12[BPh_4]_2$, $13[BPh_4]_2$, and $14[CIO_4]_2$ show, that the ferrocenyl carboxylates act as bidentate (9, 10) or bis-bidentate (12–14) bridging ligands towards one or two biotahedral LM$_2$ subunits, respectively. The structures are retained in solution as indicated by NMR spectroscopic studies on the diamagnetic ferrocencarboxylate [ClO$_4$]. All complexes were found to exhibit a rich redox chemistry. Complexation of the ferrocencarboxylates by the LM$_2$ fragments results in large potential shifts of the ferrocenyl-centred redox process. The redox processes of the LM$_2$ units are also affected upon complex formation, showing that the electron transfer events of the ferrocenyl moiety and the binuclear subunit influence one another. In 14, however, the two dinuclear cobalt(II) subunits behave as two independent redox-groups owing to the large distance between them. Additionally, we found that the magnetic properties in the pentanuclear Ni$_4$Fe complex 13 are based on the ferromagnetic exchange interactions between the Ni$^{II}$ ions in the binuclear subunits. The coupling across the metallocene dicarboxylate bridge is negligible. These results can now be used as a guide for further studies aimed at the synthesis of polynuclear complexes with novel electronic and magnetic properties.
The first member of a new class of inclusion complex composed of encapsulating metallocavitands and naphthalene diimide units were found to exhibit a rich redox chemistry. Complexation of the naphthalene diimide dicarboxylate by the Ni₂L fragments results in a cathodic potential shift of the diimide-centered redox process. The two dinuclear nickel (II) subunits behave as two independent redox-groups owing to the large distance of ca. 19 Å between them. These results can now be used as a guide for further studies aimed at a more complete encapsulation of the naphthalene diimide subunits, its photochemical properties and future developments in optoelectronics.
